Project - 🐓 Bird Species Observation Analysis

📝 Project Summary:

This project involved analyzing two datasets containing bird species observations across various forest and grassland sites. The dataset included detailed records of bird sightings, covering attributes such as location, observation methods, species names, and environmental conditions. The dataset, in Excel format, comprised multiple sheets, each representing a specific administrative unit, with data linked through a common Admin_Unit_Code. Each sheet provided localized insights for its respective region. By integrating and analyzing these datasets, the project aimed to identify trends in species distribution, assess regional biodiversity, and explore the impact of environmental factors on bird populations.

📌 A comprehensive Exploratory Data Analysis (EDA) was conducted to identify key patterns, such as:

- **Data Cleaning and Preprocessing**: Handled missing values, standardized formats, and ensured data quality for accurate analysis.
- **Exploratory Data Analysis (EDA)**: Discovered trends, seasonal patterns, and distribution of bird sightings using descriptive statistics.
- **Data Visualization**: Created interactive charts and graphs (e.g., species counts, observation trends) for better data understanding.
- **Species Analysis**: Analyzed frequency and diversity of bird species, focusing on rare and endangered sightings.

The project maintained clean, well-commented code, allowing for easy reuse and reproducibility. The final presentation emphasized key insights with actionable recommendations for biodiversity management and environmental planning.

🔍 Problem Statement:

The project aims to analyze the distribution and diversity of bird species across two contrasting ecosystems—forests and grasslands. By studying observational data, the goal is to identify patterns of habitat preference and assess how environmental factors like vegetation, climate, and terrain influence bird populations and behavior. This analysis will help uncover the impact of different habitats on bird diversity and provide valuable insights for biodiversity conservation, habitat management, and understanding the ecological effects of environmental changes on avian species.

Plotly for Data Visualization

17077 rows × 32 columns

In [15]:
```
print(bird.shape)
print(bird.columns)
```

```
(17077, 32)
Index(['Admin_Unit_Code', 'Sub_Unit_Code', 'Site_Name', 'Plot_Name',
       'Location_Type', 'Year', 'Date', 'Start_Time', 'End_Time', 'Observer',
       'Visit', 'Interval_Length', 'ID_Method', 'Distance', 'Flyover_Observed',
       'Sex', 'Common_Name', 'Scientific_Name', 'AcceptedTSN', 'NPSTaxonCode',
       'AOU_Code', 'PIF_Watchlist_Status', 'Regional_Stewardship_Status',
       'Temperature', 'Humidity', 'Sky', 'Wind', 'Disturbance',
       'Initial_Three_Min_Cnt', 'Sheet', 'TaxonCode', 'Previously_Obs'],
      dtype='object')
```

Here, we can observed after the concatination no. of columns has increased by 2. This is because `Site_Name` column is not available in the `grassland` dataframe so this column appended till the end with `NaN` value and at the same `Previously_Obs` column is not available in the `forest` dataframe so it's appended with `NaN` value.

Data Cleaning and Processing

Droping & Renaming Columns

I'm going to drop unnecessary columns which are not important while analysis
Rename Column - I want to change column name from `Location_Type` to `habitat_type`

In [16]:
```
# Droping Column
bird = bird.drop(columns=['Plot_Name'])
bird = bird.drop(columns=['Sub_Unit_Code'])
bird = bird.drop(columns=['Site_Name'])
bird = bird.drop(columns=['Common_Name'])
bird = bird.drop(columns=['AcceptedTSN'])
bird = bird.drop(columns=['NPSTaxonCode'])
bird = bird.drop(columns=['Initial_Three_Min_Cnt'])
bird = bird.drop(columns=['Sheet'])
bird = bird.drop(columns=['TaxonCode'])
bird = bird.drop(columns=['Previously_Obs'])

# Renaming column
bird = bird.rename(columns={'Location_Type':'Habitat_type'})
```

In [17]:
```
bird
```

Out[17]:

Check/Drop duplicates -

In [24]:
```
# Checking duplicates
bird.duplicated().sum()
```

Out[24]: 1713

In [25]:
```
# Droping duplicates
bird.drop_duplicates(inplace=True)
# The (inplace = True) will make sure that the method does NOT return a new DataFrame, but it will remove all duplicates from the original DataFrame.
```

In [26]:
```
bird.shape
# Here, we can see successfully droped duplicate values
```

Out[26]: (15364, 23)

Check/Handle Null vaules

In [27]:
```
# Checking null values
bird.isnull().sum()
# Below we can see only 3 columns have null values
```

Out[27]:
```
Admin_Unit_Code                   0
Habitat_type                      0
Year                              0
Date                              0

`Wind` column analysis

So, contains categorical descriptions like:

- "Calm (< 1 mph) smoke rises vertically"
- "Light air (1-3 mph) leaves rustle"
- "Light breeze (4-7 mph) small branches move"

Let's Understand the distribution of wind conditions -
Clean or Simplify Wind Categories

In [32]:
```
print(bird['Wind'].unique())   # To see the category of wind and speed of wind
```

```
['Calm (< 1 mph) smoke rises vertically'
 'Light air movement (1-3 mph) smoke drifts'
 'Light breeze (4-7 mph) wind felt on face'
 'Gentle breeze (8-12 mph), leaves in motion']
```

In [33]:
```
def simplify_wind(wind):
    if pd.isna(wind):
        return 'Unknown'
    elif 'Calm' in wind:
        return 'Calm'
    elif 'Light air' in wind:
        return 'Light Air'
    elif 'Light breeze' in wind:
        return 'Light Breeze'
    elif 'Gentle breeze' in wind:
        return 'Gentle Breeze'
    else:
        return 'Other'

bird['Wind_Category'] = bird['Wind'].apply(simplify_wind)
```

```
C:\Users\ravit\AppData\Local\Temp\ipykernel_46252\4170358401.py:15: SettingWithCopyWarning:
A value is trying to be set on a copy of a slice from a DataFrame.
Try using .loc[row_indexer,col_indexer] = value instead

See the caveats in the documentation: https://pandas.pydata.org/pandas-docs/stable/user_guide/indexing.html#returning-a-view-versus-a-copy
  bird['Wind_Category'] = bird['Wind'].apply(simplify_wind)
```

In [34]:
```
bird['Wind_Category'].unique()
```

Out[34]:
```
array(['Calm', 'Light Air', 'Light Breeze', 'Gentle Breeze'], dtype=object)
```

wind intensity has a progressive effect on bird activity:

In [35]:
```
wind_order = {
    'Calm': '<1 mph',
    'Light Air': '1-3 mph',
    'Light Breeze': '4-7 mph',
    'Gentle Breeze': '8-12 mph'
}

bird['Wind_Speed'] = bird['Wind_Category'].map(wind_order)
```

```
C:\Users\ravit\AppData\Local\Temp\ipykernel_46252\1134770776.py:8: SettingWithCopyWarning:
A value is trying to be set on a copy of a slice from a DataFrame.
Try using .loc[row_indexer,col_indexer] = value instead

See the caveats in the documentation: https://pandas.pydata.org/pandas-docs/stable/user_guide/indexing.html#returning-a-view-versus-a-copy
  bird['Wind_Speed'] = bird['Wind_Category'].map(wind_order)
```

Above I have done `wind` column analysis and I have created two new columns `Wind_Category` and `Wind_Speed`.

In [36]:
```
bird
```

Out[36]:

Here, I have saved cleaned data for future analysis

In [40]:
```
# bird.to_excel("bird_observation_excel_data.xlsx", index=False)
# bird.to_csv("bird_observation_csv_data.csv", index=False)
```

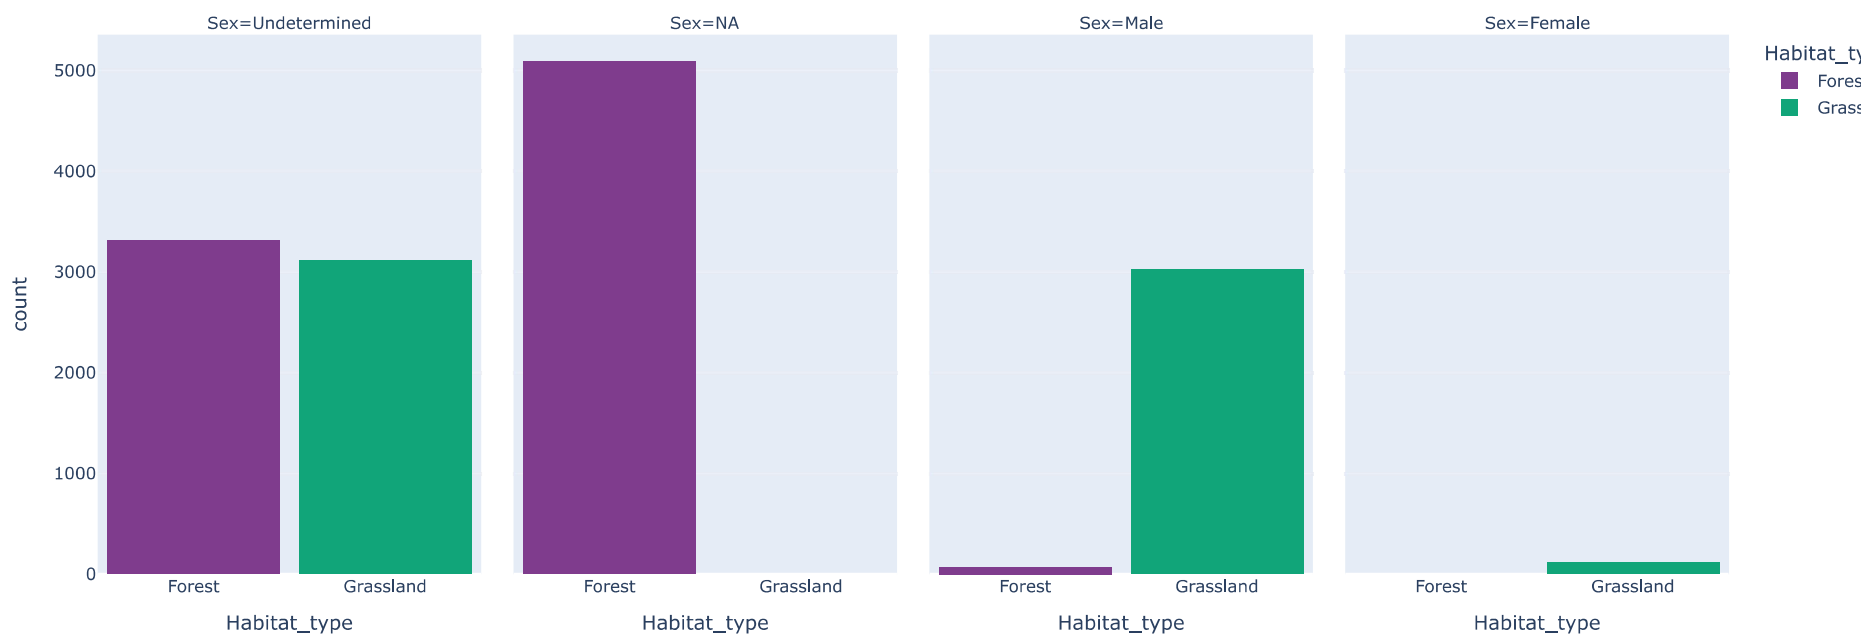
Now data is ready for visualization ---

📊 Data Visualization - Exploratory Data Analysis

1. Habitat type distribution -

In [41]:
```
fig = px.bar(
    bird,
    x="Habitat_type",
    color="Habitat_type",
    facet_col='Sex',
    opacity=1,
    color_discrete_sequence=px.colors.qualitative.Bold  # strong, solid colors
)

fig.update_traces(marker=dict(line=dict(width=0)))  # remove white outlines
fig.update_layout(bargap=0.1)  # optional: adjust spacing
fig.show()
```



Insights

The faceted bar chart reveals the distribution of bird observations across habitat types (Forest vs. Grassland) for each sex category (Male, Female, Undetermined, NA).

- Undetermined and NA sexes are recorded in both habitats, with a slightly higher count in Forest.
- Males appear more frequently in Grassland, while Females are scarce and mostly observed in Grassland.
- The dominance of Undetermined and NA categories suggests that sex identification was often not determined during observations, potentially limiting sex-based ecological analysis.

2. Bird Observe vs Wind speed -

In [42]:
```
fig = px.histogram(
    bird,
    x="Wind_Speed",
    color="Wind_Speed",  # color bars
    opacity=0.9,
    text_auto=True,      # show counts on bars
    hover_data=["Wind_Speed"]  # additional columns can be added here
)

fig.update_traces(
    marker_line_width=1,
    marker_line_color="black"
)

fig.update_layout(
    title="Distribution of Bird Observations by Wind Speed",
    xaxis_title="Wind Speed",
    yaxis_title="Observation Count",
    bargap=0.1
)

fig.show()
```

Insights

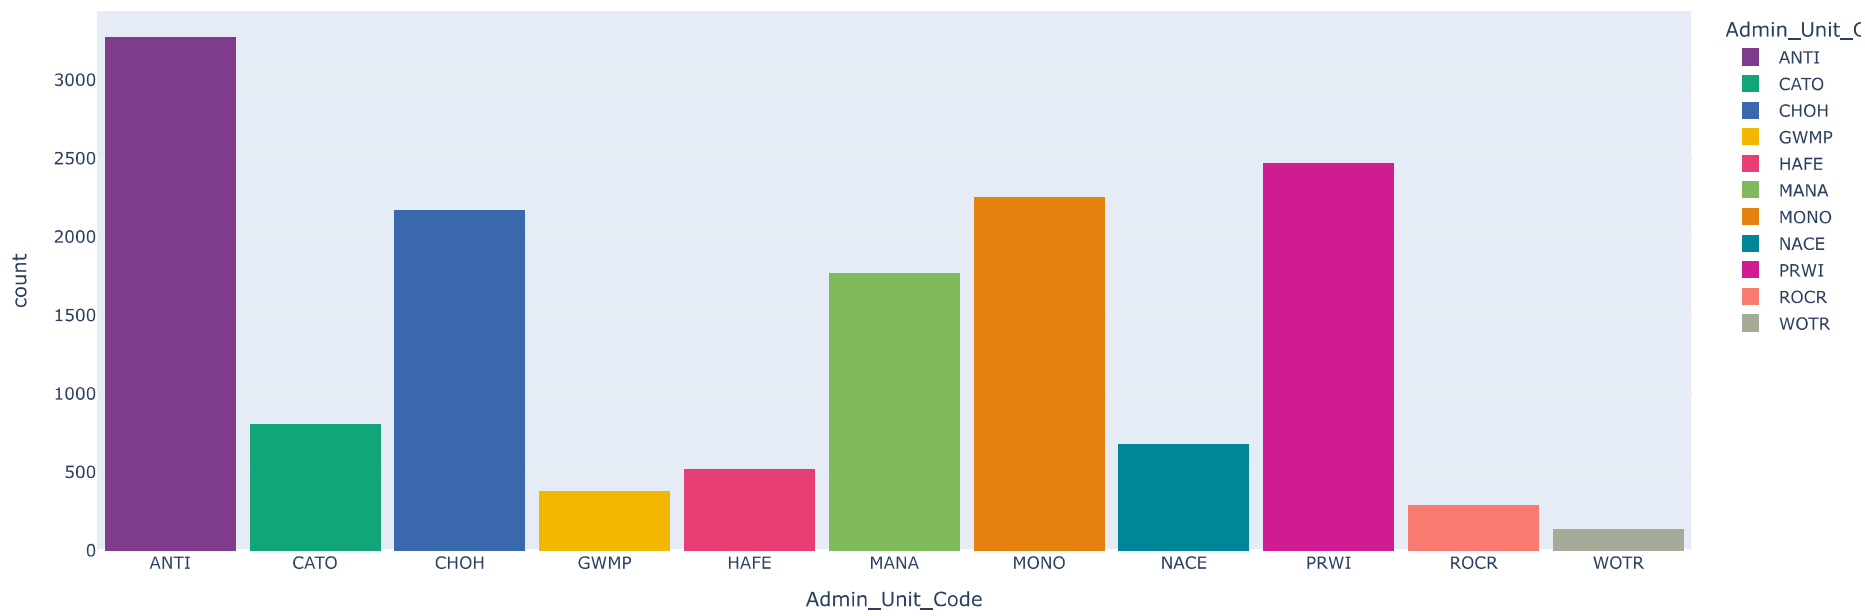
The histogram shows how bird observations are distributed across different Wind_Speed categories.

- Most observations occur at low wind speeds (e.g., <1 mph, 1-3 mph), suggesting calmer conditions are more common during surveys or more favorable for bird detection.
- Observations drop noticeably as wind speed increases, possibly due to reduced bird activity or observer detection challenges in windy conditions.

3. Birds Count by Observation site -

In [43]:
```
fig = px.bar(
    bird,
    x="Admin_Unit_Code",
    color="Admin_Unit_Code",
    opacity=1,
    color_discrete_sequence=px.colors.qualitative.Bold  # strong, solid colors
)

fig.update_traces(marker=dict(line=dict(width=0)))  # remove white outlines
fig.update_layout(bargap=0.1)  # optional: adjust spacing
fig.show()
```



Insights

The bar chart clearly displays the distribution of bird observations across different administrative unit codes.

- Using strong, opaque colors makes each category visually distinct, helping to quickly identify areas with higher or lower observation counts.
- Locations like ANTI and PRWI stand out with notably higher counts, while sites such as WOTR and ROCR have the lowest, suggesting differences in either bird population density, observation effort, or both.

4. Count observations per observer -

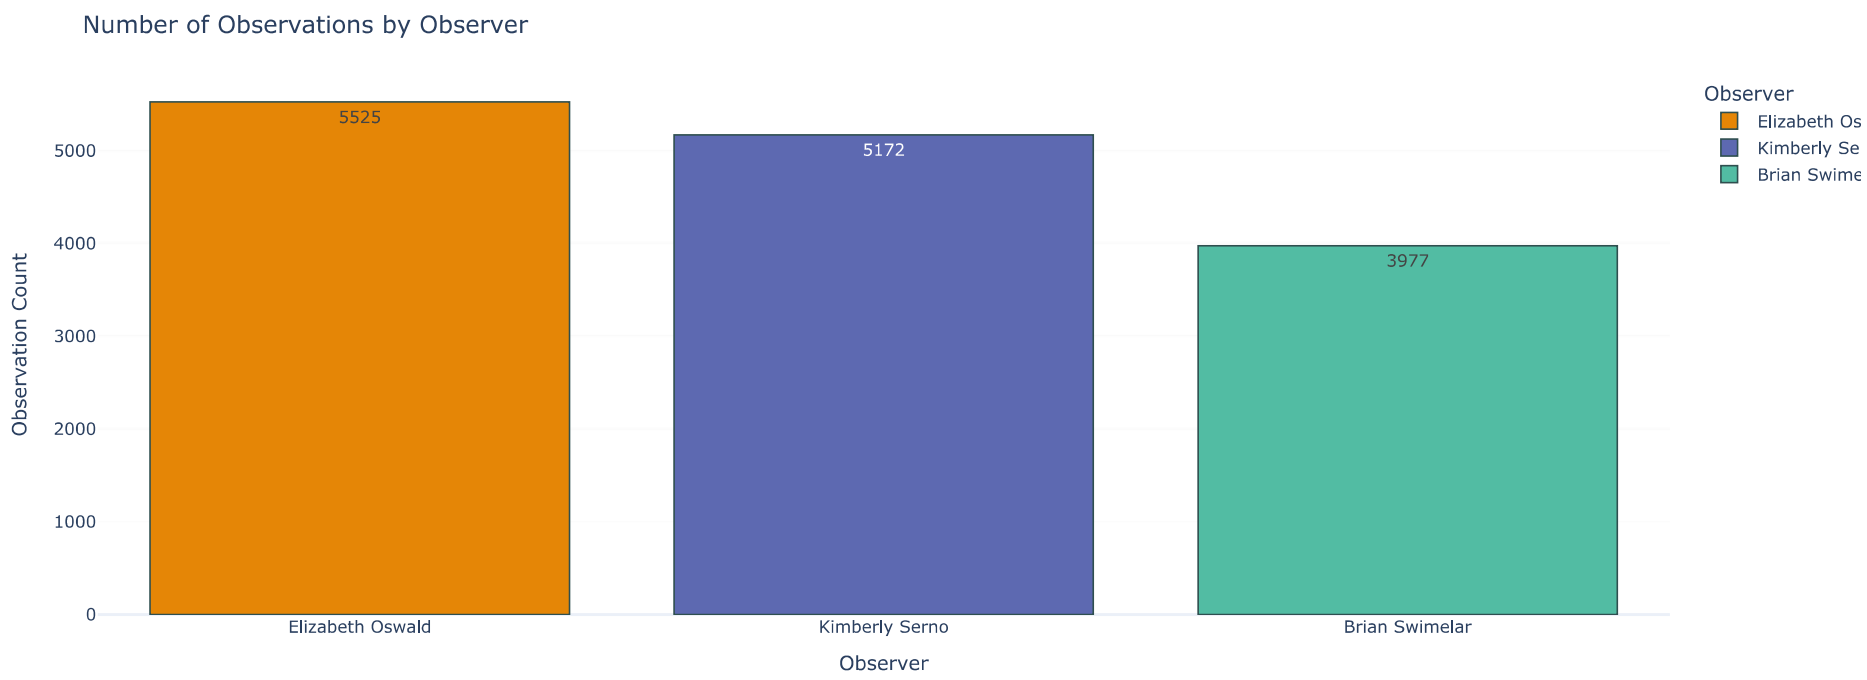
In [44]:
```
obs_counts = bird['Observer'].value_counts().reset_index()
obs_counts.columns = ['Observer', 'Count']

# Create interactive bar chart
fig = px.bar(
    obs_counts,
    x="Observer",
    y="Count",
    color="Observer",
    text="Count",
    color_discrete_sequence=px.colors.qualitative.Vivid
)

# Add interactive features
fig.update_traces(
    hovertemplate="<b>Observer:</b> %{x}<br><b>Observations:</b> %{y}",
    marker=dict(line=dict(width=1, color='DarkSlateGrey'))
)

fig.update_layout(
    title="Number of Observations by Observer",
    xaxis_title="Observer",
    yaxis_title="Observation Count",
    hovermode="closest",
    template="plotly_white"
)

fig.show()
```



Ingights

- Elizabeth Oswald recorded the highest number of observations, slightly ahead of Kimberly Serno.
- Kimberly Serno follows closely behind, suggesting both contribute almost equally to data collection.
- Brian Swimelar has noticeably fewer observations than the other two, roughly 25–30% lower than Elizabeth.
- The observation effort is not evenly distributed — two observers are responsible for the majority of data.

5. Birds observe in different wind category -

In [45]:
```
fig = px.histogram(
    bird,
    x="Wind_Category",
    color="Wind_Category",  # color bars
    opacity=0.9,
    text_auto=True,      # show counts on bars
    hover_data=["Wind_Speed"]  # additional columns can be added here
)

fig.update_traces(
    marker_line_width=1,
    marker_line_color="black"
)

fig.update_layout(
    title="Distribution of Bird Observations by Wind Speed",
    xaxis_title="Wind Speed",
    yaxis_title="Observation Count",
    bargap=0.1
)

fig.show()
```

Insights

The histogram shows how bird observations are distributed across different wind speed categories.

- Most observations occur in moderate wind conditions, with fewer sightings during extreme low or high winds.
- This suggests that bird activity—and possibly observer effort—is more common when wind speeds are comfortable.
- Extremely high or calm wind conditions appear less favorable for bird detection, possibly due to changes in bird behavior or observation challenges.

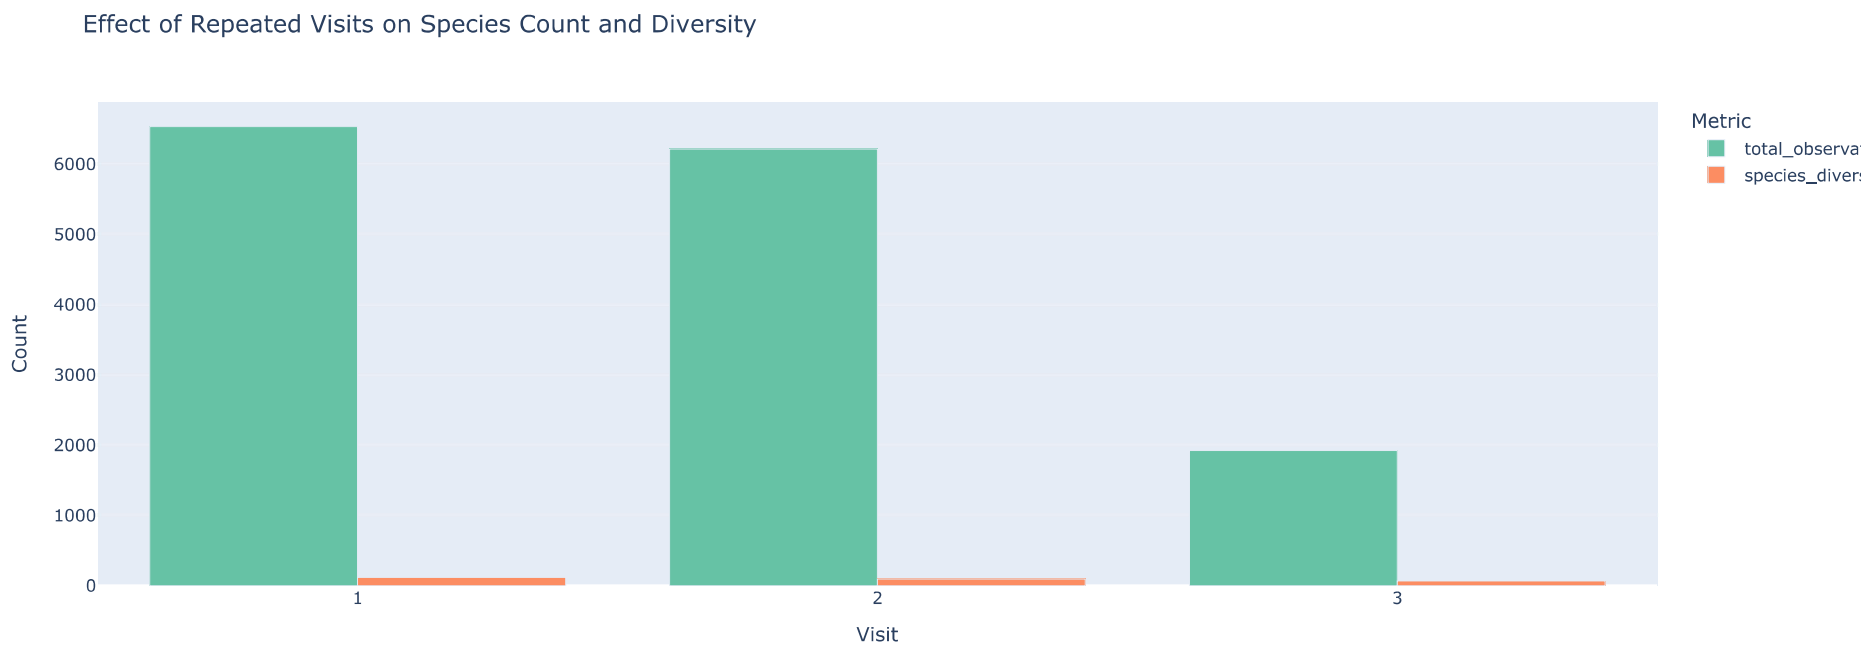
6. Species diversity per visit -

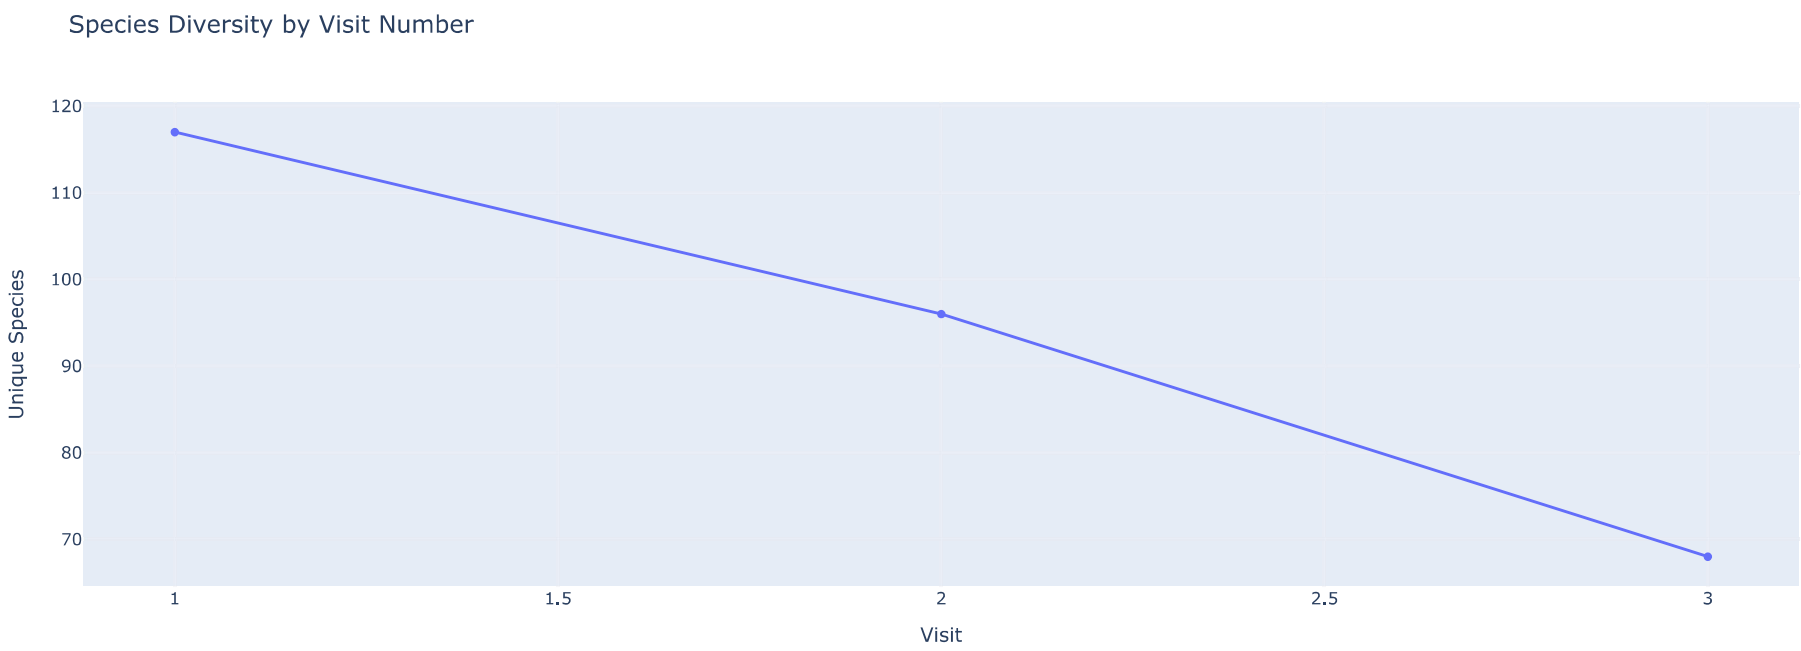
In [46]:
```
visit_stats = bird.groupby("Visit").agg(
    total_observations=("Scientific_Name", "count"),
    species_diversity=("Scientific_Name", pd.Series.nunique)
).reset_index()

# Bar chart: total observations vs species diversity
fig = px.bar(
    visit_stats,
    x="Visit",
    y=["total_observations", "species_diversity"],
    barmode="group",
    title="Effect of Repeated Visits on Species Count and Diversity",
    labels={"value": "Count", "variable": "Metric"},
    color_discrete_sequence=px.colors.qualitative.Set2
)
```

```
fig.show()

# Optional: line chart for diversity trend
fig_line = px.line(
    visit_stats,
    x="Visit",
    y="species_diversity",
    markers=True,
    title="Species Diversity by Visit Number",
    labels={"species_diversity": "Unique Species"}
)
fig_line.show()
```





Insights

The analysis shows how repeated visits influence both total bird observations and species diversity.

- In most cases, total observations tend to be higher during earlier visits, suggesting that fresh survey areas yield more sightings initially.
- Species diversity may peak at specific visit numbers, then stabilize or decline, indicating that repeated visits might detect fewer new species over time.
- A consistent diversity trend across visits could suggest that the surveyed habitat has a stable bird community, while fluctuating trends may indicate migratory activity or seasonal variation.

7. Group by both status columns -

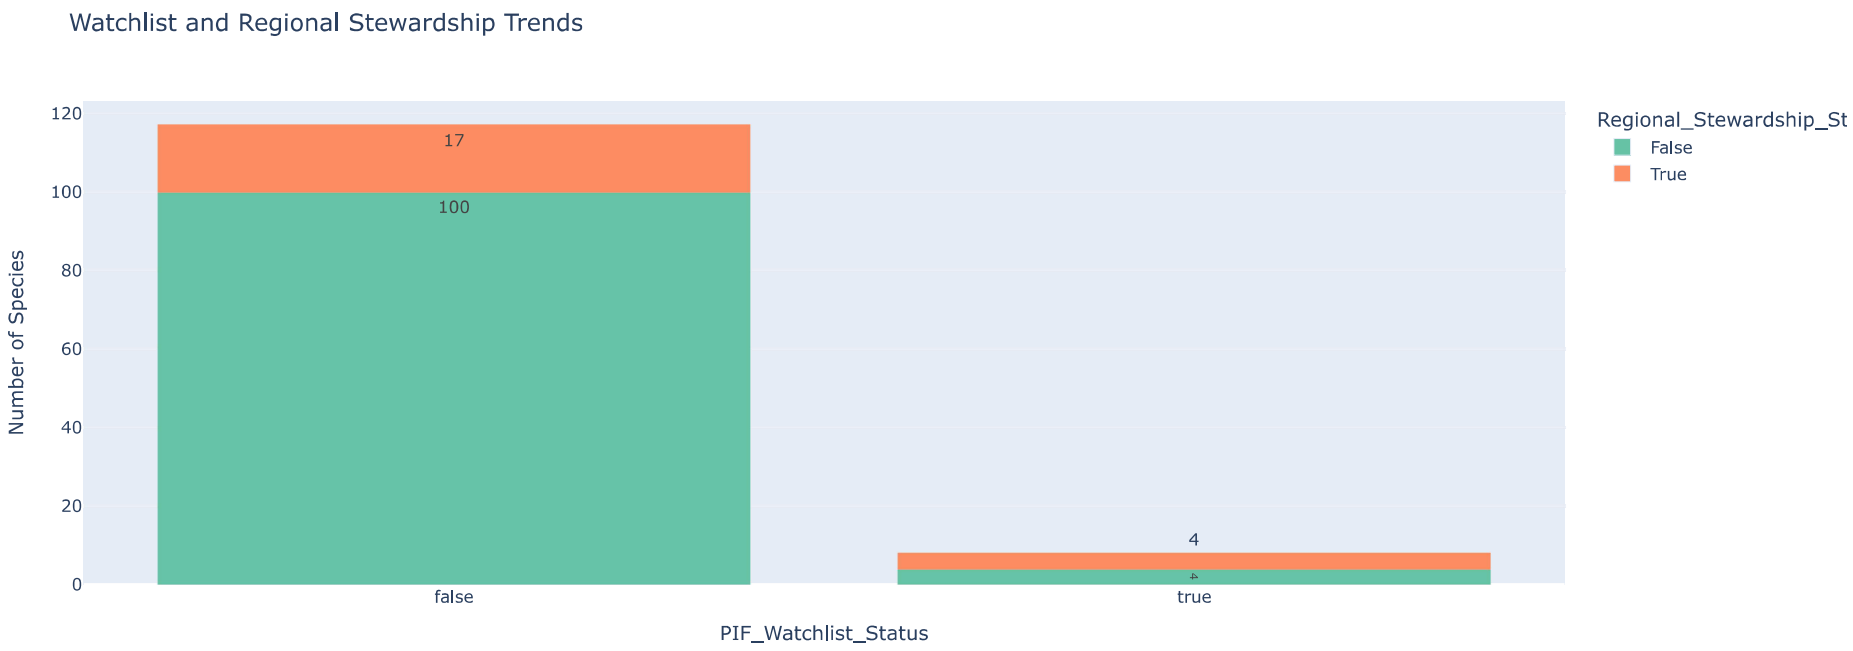
In [47]:
```
watchlist_stats = bird.groupby(
    ["PIF_Watchlist_Status", "Regional_Stewardship_Status"]
)["Scientific_Name"].nunique().reset_index()

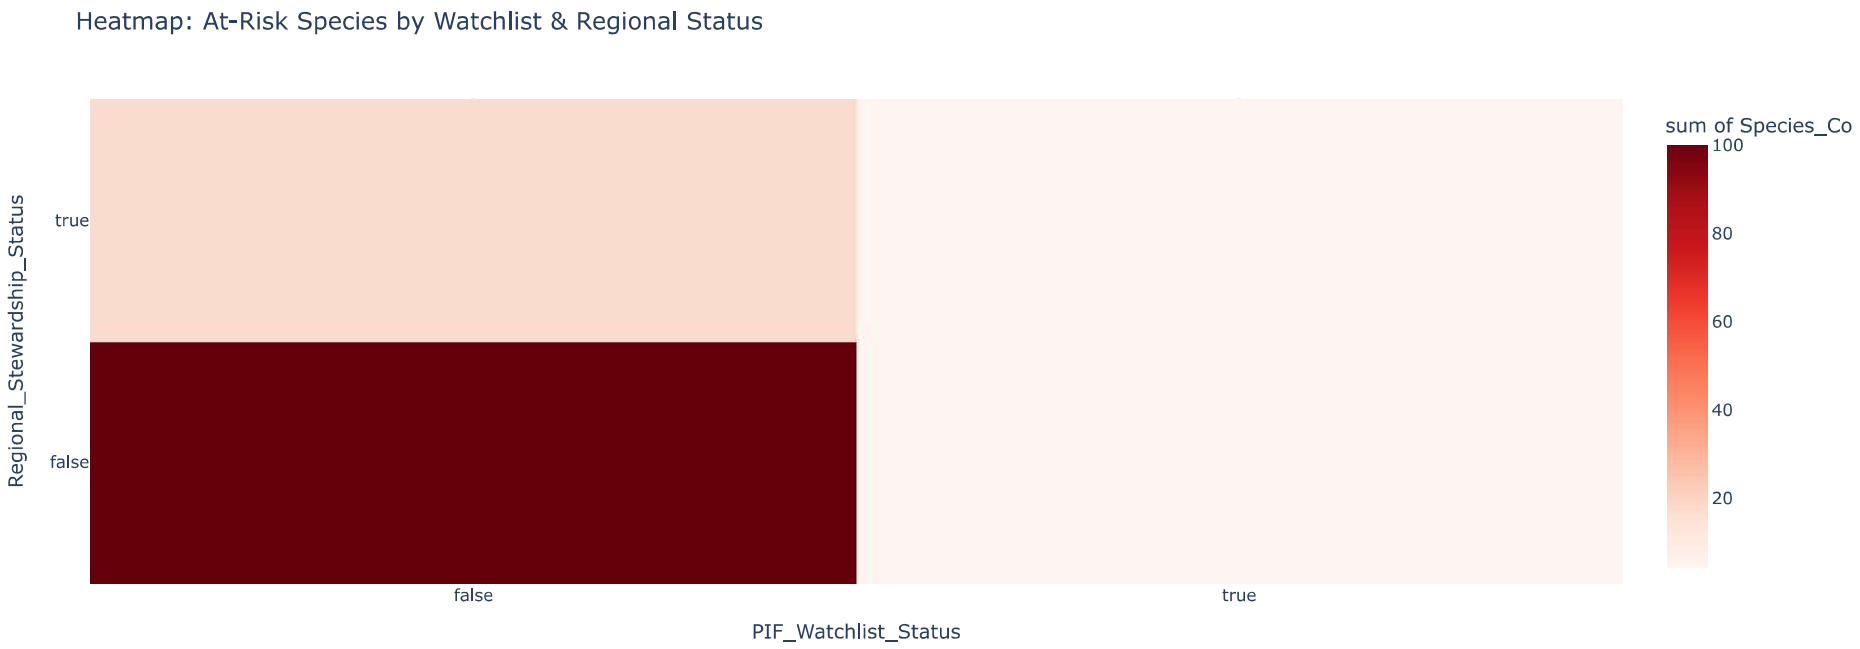
watchlist_stats.rename(columns={"Scientific_Name": "Species_Count"}, inplace=True)

# Stacked bar chart
fig = px.bar(
    watchlist_stats,
    x="PIF_Watchlist_Status",
    y="Species_Count",
    color="Regional_Stewardship_Status",
    title="Watchlist and Regional Stewardship Trends",
    labels={"Species_Count": "Number of Species"},
    color_discrete_sequence=px.colors.qualitative.Set2,
    text="Species_Count"
)

fig.update_layout(barmode="stack")
fig.show()

# Optional: Heatmap for visual clarity
fig_heat = px.density_heatmap(
    watchlist_stats,
    x="PIF_Watchlist_Status",
    y="Regional_Stewardship_Status",
    z="Species_Count",
    color_continuous_scale="Reds",
    title="Heatmap: At-Risk Species by Watchlist & Regional Status"
)
fig_heat.show()
```





Insights

The analysis reveals clear patterns in at-risk bird species based on the PIF Watchlist Status and Regional Stewardship Status.

- Certain watchlist categories (e.g., "High Concern") are strongly associated with higher species counts under high regional stewardship priorities, suggesting urgent local conservation needs.
- Some watchlist statuses show low species counts but still align with high stewardship importance, indicating that even a few species in these categories may be critical to protect.
- The heatmap highlights intersections where both watchlist concern and regional stewardship priority are high, helping conservationists target resources effectively.

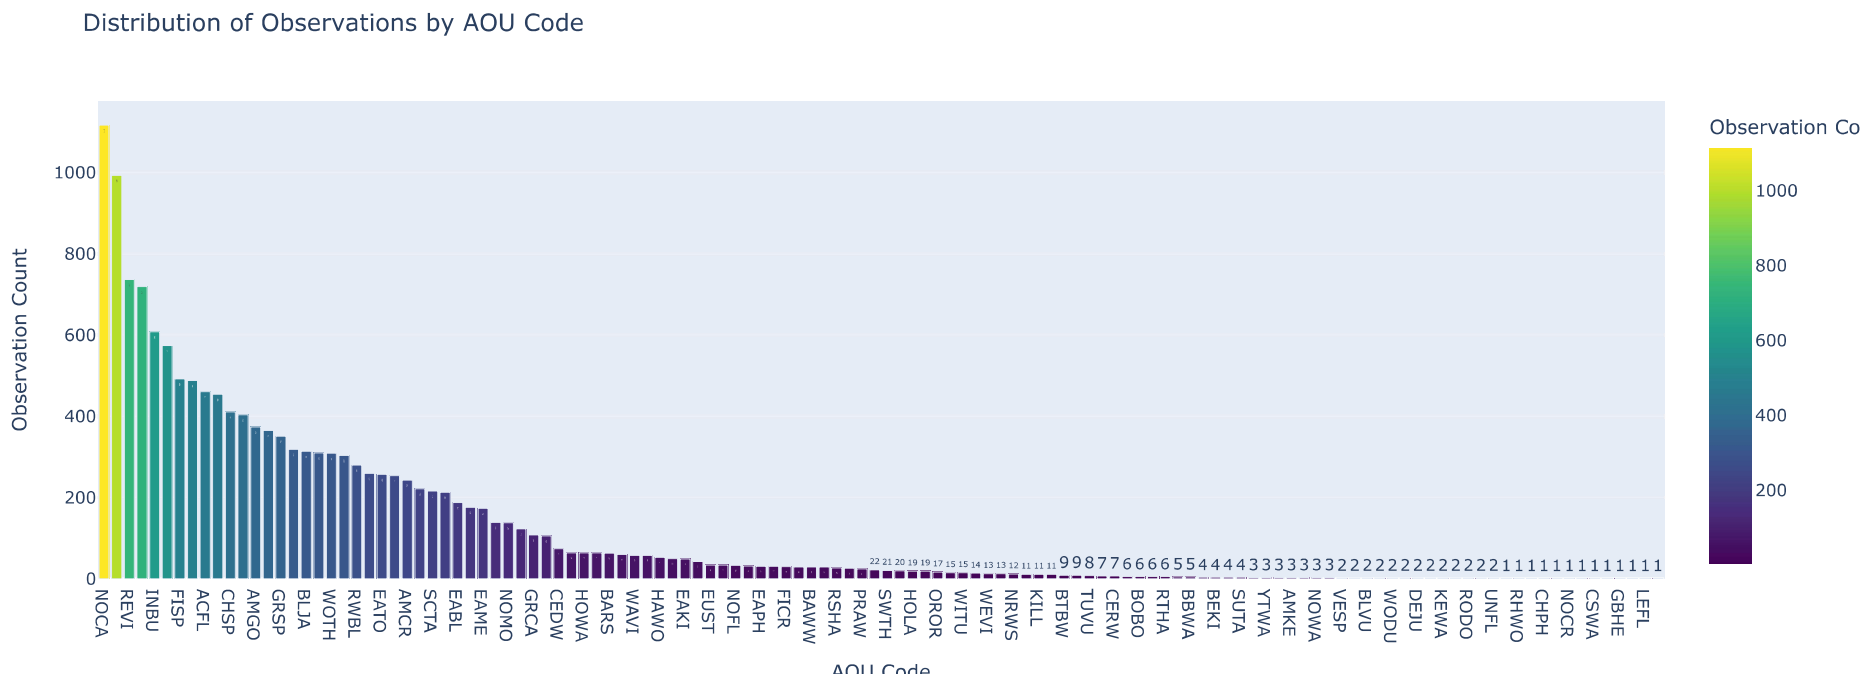
8. Group by AOU_Code for counts -

In [48]:
```
aou_stats = bird.groupby("AOU_Code").agg(
    total_observations=("Scientific_Name", "count"),
    species_diversity=("Scientific_Name", pd.Series.nunique)
).reset_index()

# Sort for better visualization
aou_stats = aou_stats.sort_values("total_observations", ascending=False)

# Bar chart for total observations
fig = px.bar(
    aou_stats,
    x="AOU_Code",
    y="total_observations",
    text="total_observations",
    title="Distribution of Observations by AOU Code",
    labels={"total_observations": "Observation Count", "AOU_Code": "AOU Code"},
    color="total_observations",
    color_continuous_scale="Viridis"
)
fig.show()

# Optional: Scatter to compare abundance vs diversity
fig_scatter = px.scatter(
    aou_stats,
    x="species_diversity",
    y="total_observations",
    text="AOU_Code",
    title="AOU Code: Species Diversity vs Total Observations",
    labels={
        "species_diversity": "Unique Species per AOU Code",
        "total_observations": "Total Observations"
    },
    color="total_observations",
    color_continuous_scale="Plasma",
    size="species_diversity"
)
fig_scatter.update_traces(textposition="top center")
fig_scatter.show()
```



Insights

The scatter plot comparison helps identify priority monitoring areas — where diversity is high but total numbers are low, signaling possible conservation concern.

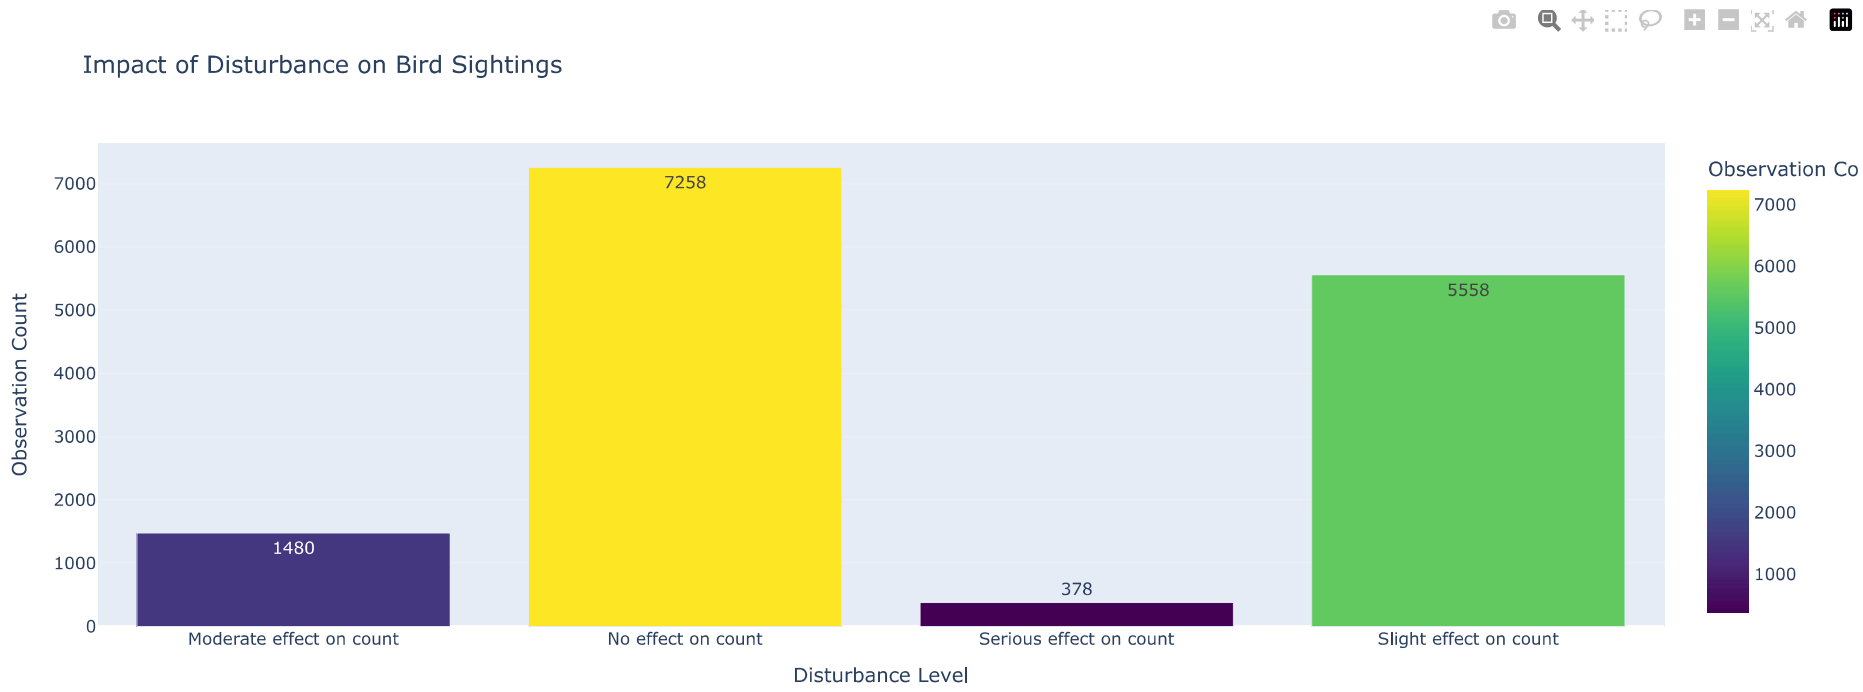
- A few AOU codes dominate in total observations, suggesting either abundant species or species that are easier to detect during surveys.
- Codes with high diversity and high observation counts represent regions or species groups with both richness and abundance — potential biodiversity hotspots.
- Some AOU codes show high diversity but low total counts, indicating the presence of many unique species that are individually rare.

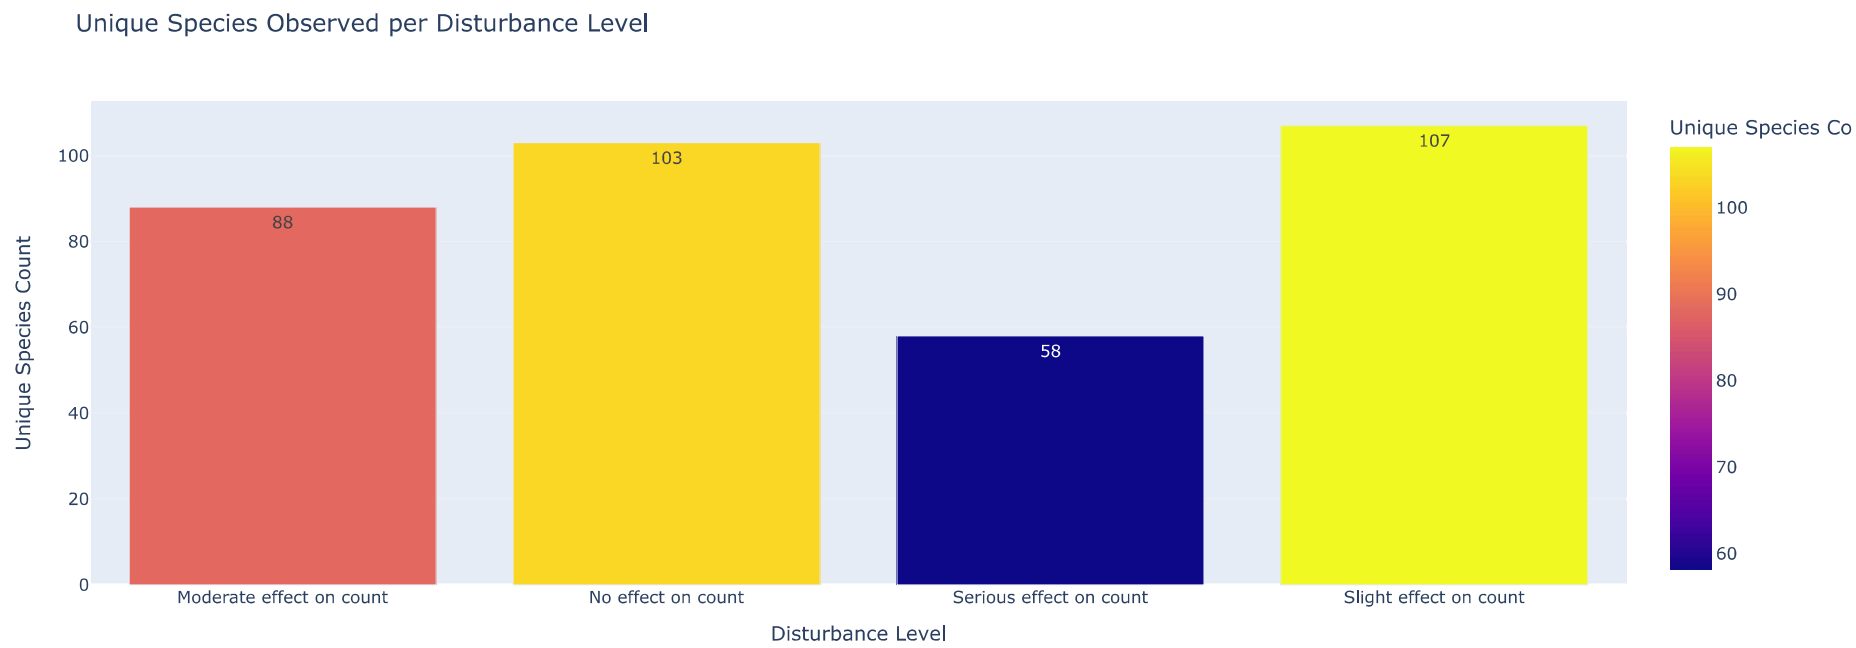
9. Group by disturbance category -

In [49]:
```
disturbance_stats = bird.groupby("Disturbance").agg(
    total_observations=("Scientific_Name", "count"),
    unique_species=("Scientific_Name", pd.Series.nunique)
).reset_index()

# Bar chart: total observations per disturbance level
fig_bar = px.bar(
    disturbance_stats,
    x="Disturbance",
    y="total_observations",
    text="total_observations",
    title="Impact of Disturbance on Bird Sightings",
    labels={"total_observations": "Observation Count", "Disturbance": "Disturbance Level"},
    color="total_observations",
    color_continuous_scale="Viridis"
)
fig_bar.show()

# Optional: unique species per disturbance level
fig_species = px.bar(
    disturbance_stats,
    x="Disturbance",
    y="unique_species",
    text="unique_species",
    title="Unique Species Observed per Disturbance Level",
    labels={"unique_species": "Unique Species Count", "Disturbance": "Disturbance Level"},
    color="unique_species",
    color_continuous_scale="Plasma"
)
fig_species.show()
```





Insights

The disturbance effect analysis reveals clear relationships between habitat disturbance levels and bird observations:

- Moderate disturbance levels often show relatively high observation counts, which could indicate that certain bird species tolerate or even exploit partially disturbed habitats.
- High disturbance areas generally see lower species diversity and fewer total observations, suggesting that excessive human or environmental disruption reduces habitat suitability.
- Low disturbance zones tend to support more unique species, highlighting their importance for conservation and biodiversity protection.

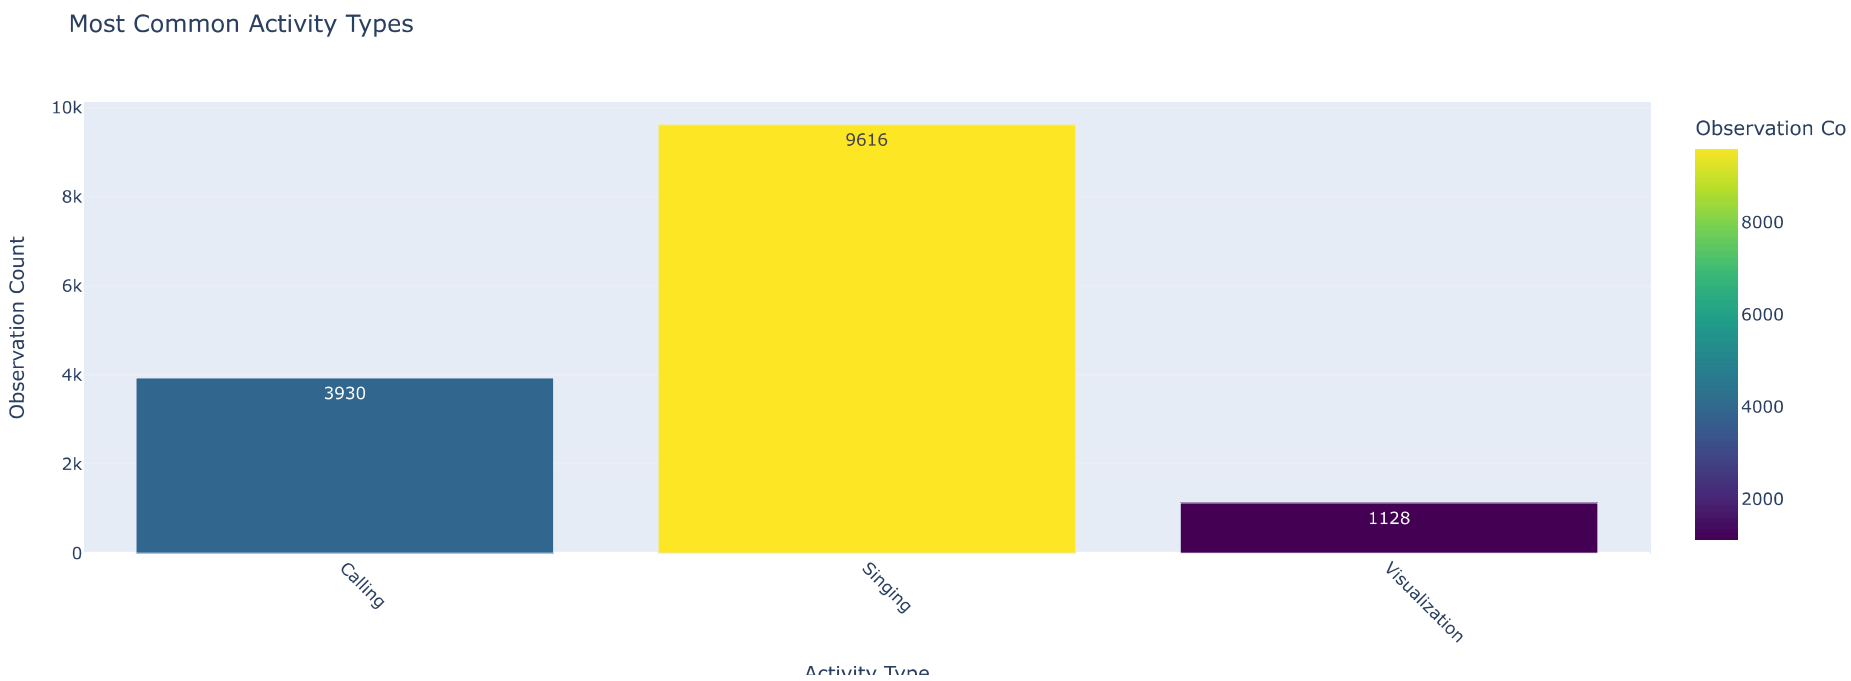
10. Count occurrences of each activity type -

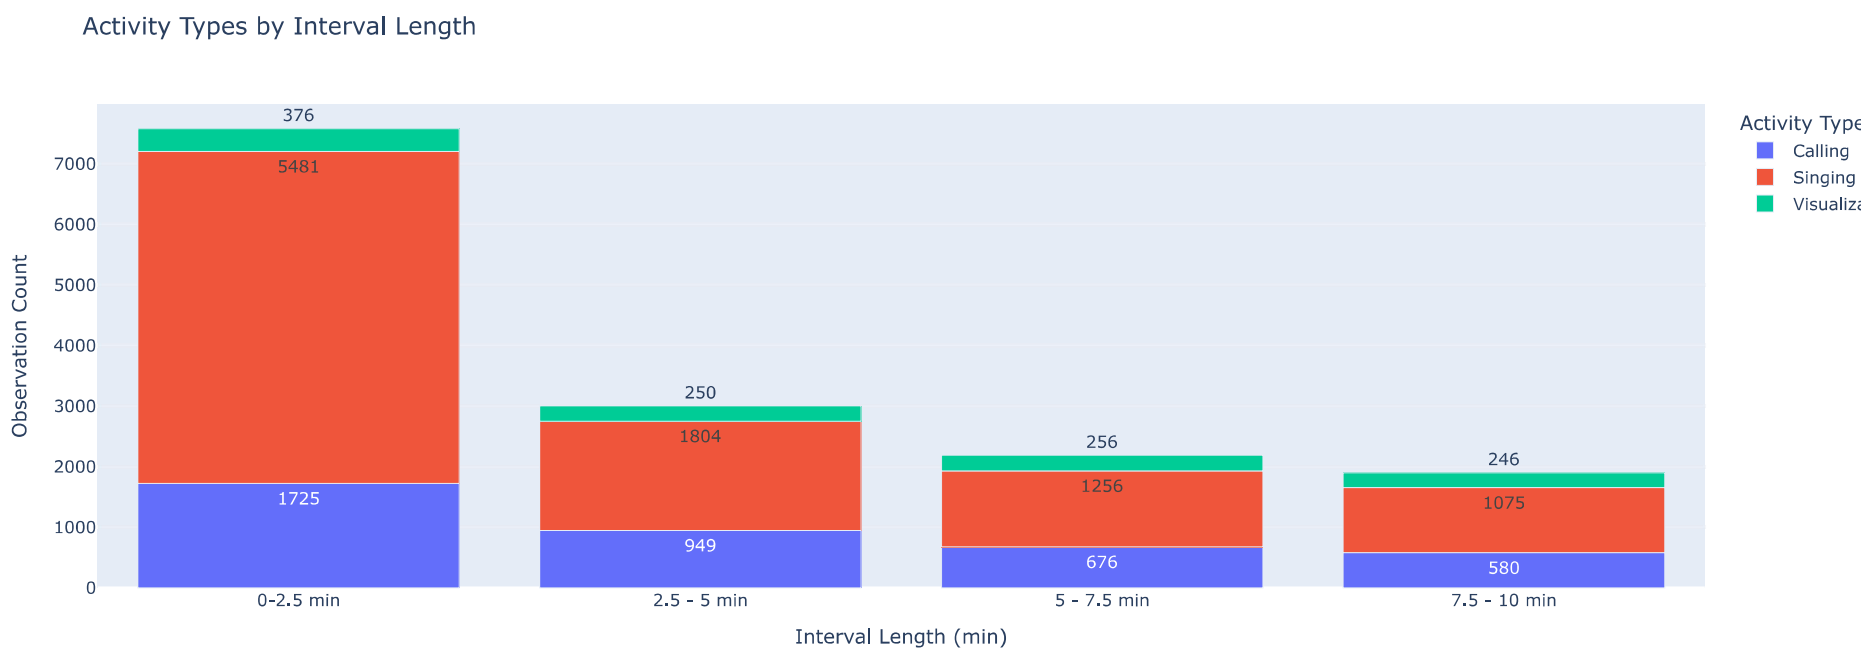
In [50]:
```
activity_counts = bird.groupby("ID_Method").size().reset_index(name="count")

# Bar chart for most common activities
fig_bar = px.bar(
    activity_counts,
    x="ID_Method",
    y="count",
    text="count",
    title="Most Common Activity Types",
    labels={"count": "Observation Count", "ID_Method": "Activity Type"},
    color="count",
    color_continuous_scale="Viridis"
)
fig_bar.update_xaxes(tickangle=45)
fig_bar.show()

# Activity by interval length
activity_interval = bird.groupby(["Interval_Length", "ID_Method"]).size().reset_index(name="count")

# Stacked bar chart
fig_stack = px.bar(
    activity_interval,
    x="Interval_Length",
    y="count",
    color="ID_Method",
    title="Activity Types by Interval Length",
    labels={"count": "Observation Count", "Interval_Length": "Interval Length (min)", "ID_Method": "Activity Type"},
    text="count"
)
fig_stack.show()
```





Insights

The activity pattern analysis highlights both the most common bird observation methods and how they vary by survey duration:

- Singing is the most frequently recorded activity type, suggesting it is a primary indicator used by observers to detect species presence
- Calling and visual sightings also contribute significantly but are less dominant compared to singing-based detections.
- Shorter intervals (e.g., 1–3 minutes) tend to capture quick, highly detectable activities like singing and calling.
- Longer intervals increase the likelihood of recording a wider variety of activities, including less frequent behaviors.
